

Site Recordings Table — Complete Guide

OomniEye Digital Twin Solutions · Help Management System · Revision 4.2

1. Overview

The Site Recordings table is the primary interface for reviewing every capture taken on a site. Each row represents a single recording produced during a site visit, and the columns describe where it was captured, when, at what quality and how large the resulting file is.

This guide explains every column, the sorting and pagination behaviour, and the recommended workflows for auditing a large recording library.

2. Column reference

Each column can be sorted independently. Sorting is applied after filtering, so it reorders only the rows currently visible.

- Recording — the capture file name, generated from the drawing and the capture timestamp.
- Session — the visit grouping number; all captures between one check-in and check-out share a number.
- Pin — the physical location marker on the site plan, using the level and area code format (for example L2 / KL-Ar).
- Resolution — the capture resolution recorded by the device.
- Started / Closed At — the boundary timestamps of the capture.
- Duration — total recorded length.
- Size — the stored file size after processing.

3. Sorting and pagination

Click any column header to sort ascending; click again to reverse. The active sort is indicated by a caret next to the header label.

The table paginates in fixed page sizes. The footer always states the visible range and the total count so you can confirm nothing has been silently filtered out.

4. Searching

The search field matches on recording name, pin label and tags. Matching is partial and case-insensitive, so a two or three character fragment is usually enough.

- Search runs on top of the active date range.
- Clearing search restores the full filtered list.
- Search never modifies saved filters.

5. Filtering

Filters are consolidated into a single Filter control. Selections apply immediately and the active filter count appears on the control itself.

- Date range — restrict to a rolling window or an explicit range.
- Resolution — narrow to a specific capture quality.
- Duration — exclude very short or unusually long captures.
- Tags — include only captures carrying the selected tags.

6. Troubleshooting

If an expected recording is missing, widen the date range first — the default rolling window is the most common cause of an apparently missing capture.

If a recording shows a zero duration, the capture was interrupted before the device closed the session. Re-capture is required; the partial file is retained for reference only.

7. Best practice

- Audit by session rather than by file when reconciling a site visit.
- Export the filtered view before making bulk changes.
- Use list view for auditing and grid view for visual recognition.
